

Case Study: Online Food Delivery Order Management System

Scenario

An **online food delivery platform** wants to manage customer orders.

Each order contains:

Order ID

Customer Name

Food Items Ordered

Total Bill

The system allows the restaurant manager to:

Add a new order

Add food items to the order

Remove an item from the order

Display all orders

Search order by Order ID

Remove an order after delivery

Sample Program Execution

Step 1: Add a New Order

Sample Input

Enter Order ID: 101

Enter Customer Name: Ravi

Sample Output

Order created successfully

Step 2: Add Food Items

Sample Input

```
Enter food item: Burger
Enter item price: 150
```

```
Enter food item: Pizza
Enter item price: 300
```

Sample Output

```
Item added to order
Item added to order
```

Step 3: Remove an Item

Sample Input

```
Enter item to remove: Burger
```

Sample Output

```
Item removed from order
```

Step 4: Display All Orders

Sample Output

```
Order ID: 101
Customer: Ravi
Items: ['Pizza']
Total Bill: 450
```

(Total bill remains the sum of entered prices in this example)

Step 5: Search Order by ID

Sample Input

Enter Order ID to search: 101

Sample Output

Order Found
Customer: Ravi
Items: ['Pizza']
Total Bill: 450

Step 6: Remove Order After Delivery

Sample Input

Enter delivered order ID: 101

Sample Output

Order removed from system
Remaining Orders: {}
